

MESA treated turf is often described as being deeper green than turf fertilized with other products. This brilliant color is associated with the ammonium sulfate content. The patented MESA formulation provides ammonium sulfate in a form that does not stimulate excessive growth and reduces burn potential.

University tests have shown that MESA will deliver excellent turf while producing fewer clippings than turf fertilized with sulfur-coated urea products.

Since MESA is a combination of ammonium sulfate and LebanonTurf's highly efficient methylene urea, more of the nitrogen applied will be available to the plant. Fertilizers should deliver what you pay for.

Turf professionals often ask "How can any fertilizer that works so quickly last so long?" The answer is the combination of ammonium sulfate with methylene urea. Practical leaching tests suggest that the ammonium sulfate in MESA lasts twice as long as ammonium sulfate by itself.
